HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Molecular and isotope characterization of soil lipids along a savannah (C₄)/eucalyptus (C₃) chronosequence (Pointe-Noire, Congo)

The surfaces dedicated to forestry plantations are rapidly increasing throughout the world, especially in the tropics [1]. The impacts of such a rapid afforestation on global carbon cycle and on soil that constitutes one of its key compartment, is therefore a critical issue [2]. Stable carbon isotope characterization of C₄/C₃ chronosequences has proven useful in assessing the dynamics of organic carbon in soils [3]. Lipids are important contributors to organic matter in soils since they can influence aggregate stability, water retention and fertility. Nevertheless, little is known on the effects of afforestation on lipid composition and dynamics in tropical soils. The eucalyptus plantation located in the area of Pointe-Noire (Republic of Congo) is a prime field to study the impact of afforestation on organic carbon dynamics. Indeed, a eucalyptus forest (C₃) has been progressively planted on savannah (C₄) during the last 30 years [4]. Lipids were solvent-extracted from the top soil (0-20 cm) of stands planted for 7, 17, 30 years, and of a reference plot of the initial savannah. They were also extracted from the main savannah species and from eucalyptus.

Lipids accounted for 0.3 to 0.9 wt % of the dried soils. Gas chromatography-mass spectrometry analyses of soil lipids revealed a complex mixture comprising more than 100 identified constituents, belonging to diverse chemical families (e.g. fatty lipids, triterpenes, sterols, glycerols). Most of these molecules correspond to
plant components, emphasizing the importance of this source of organic matter to soil lipids. Afforestation did not appear to affect significantly bulk lipid yields. Most of the identified components are present all along the chronosequence. Nevertheless, quantification of the main compounds revealed, for some of them, significant trends related to the vegetation changes: (i) decrease of savannah grasses markers (very long chain fatty lipids, pentacyclic triterpene methyl ethers), (ii) increase of eucalyptus contribution (long chain fatty lipids) and (iii) increase of microbial marker (cholesterol). Compound-specific $\delta^{13}$C analyses were performed (1) on odd carbon chain length $n$-alkanes from 25 to 31 carbon atoms that are specific to higher plants and common to both vegetations and (2) on savannah grass markers. After 30 yrs of eucalyptus crop, the $\delta^{13}$C of soil $C_{25}$ and $C_{27}$ $n$-alkanes displayed typical trend of a $C_4/C_3$ vegetation shift with a depletion of 4.4 ‰ and 6.4 ‰ (Fig. 1). Surprisingly, the $C_{29}$ $n$-alkane $\delta^{13}$C is of -30.5 ‰ for all stands, pointing to additional sources for this compound. The isotopic signature of the $C_{31}$ $n$-alkane showed no incorporation from the eucalyptus plant, as for pentacyclic triterpene methyl ethers. Compound-specific $^{14}$C analyses are under progress to precise the origin and the residence time of the different markers in soil.

Fig. 1. $C_{25}$-alkane dynamics
